Correlational (prior work)

SD1.5 | SDXL | newer G → architecture, VAE, training data, resolution, sampler: *all differ*

compare metric(G) with Acc(G) across $G \Rightarrow$ confounded

Interventional (ours)

fixed (G, π) pool P $3N$/class → low/high D / low/high A / random mixtures → sets S (N/class) → probe → real-test acc. vs. measured D, C, A, F

only the *selection* differs $\Rightarrow$ effects attributable to set composition
